## Summary

There is an urgent need to perform multi-model studies to characterize uncertainty arising from models' heterogeneity with the aim of building a more reliable and transparent framework to inform policy makers in the design and implementation of climate policies (Guivarch et al., 2022). In response to this challenge, multiple institutes and organizations have adopted the standardized data template developed by the Integrated Assessment Modeling Consortium (IAMC). This template is maintained by the International Institute for Applied Systems Analysis (IIASA) and aims to standardize and facilitate model intercomparison exercises. For the latest Assessment Report (AR6), the Intergovernmental Panel on Climate Change (IPCC) required all contributors to homogenize their data to enable comparisons and ensure full transparency (Krey et al., 2014). This practice has set the foundation for a new open management of the outputs in the area of global scenario analysis.

In the case of the Global Change Analysis Model (GCAM) (Calvin et al., 2019), a well-regarded model that has been extensively used for different international and national scenario analysis, the harmonization code has never been documented nor standardized, making it difficult to reproduce outputs and hindering the transparency of results. To overcome these limitations, we have developed gcamreport, an R package that systematizes the transformations of GCAM outputs, generates figures to facilitate the analysis of the results, and allows user interaction with the produced outputs. Furthermore, the tool can be used embedded in a Docker image, which allows users to use the package in a virtual environment without having to install any specific software or library. Finally, each gcamreport release is linked to either a version of GCAM or a study in which GCAM was used, ensuring reproducibility, interoperability, accessibility, and findability, which is in line with the well-known open science principles FAIR and TRUST (Lin et al., 2020; Wilkinson et al., 2016).

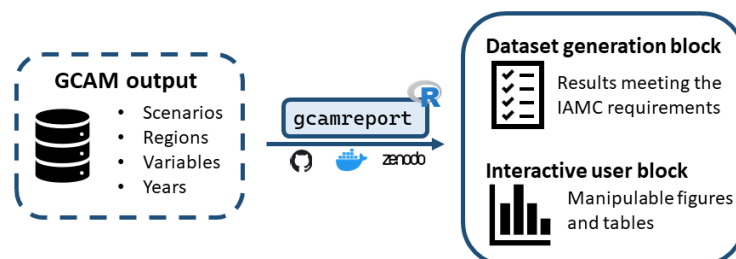

Figure 1: Structure of the gcamreport package.

The `gcamreport` package is accessible online at the public domain <https://github.com/bc3LC/gcamreport>. To run it to generate and save the dataset meeting the IAMC requirements and to launch the user interface, you can follow a detailed [step-by-step tutorial](#) or this simplified code:

```
# install the package
remotes::install_github("bc3LC/gcamreport")
library(gcamreport)

# run the main function to produce the dataset report meeting the IAMC
# requirements and launch the user interface
db_path <- "path/to/my-gcam-database"
db_name <- "my-gcam-database"
prj_name <- "my-project.dat"
scen_name <- "name of the GCAM scenarios"
generate_report(db_path = db_path, db_name = db_name, prj_name = prj_name,
scenarios = scen_name, final_year = 2100, save_output = TRUE, launch_ui = TRUE)
```

The additional instructions to run the package through a Docker image and using further functionalities can be found in the [online documentation](#) for all the release versions.

## Statement of need

Integrated assessment models (IAMs) are the dominant tools for global scenario analysis and for exploring system-wide implications of climate policies (Van Beek et al., 2020). They must be transparent and open in order to be an effective instrument for informing decision making. In addition, multi-model studies should be considered to strengthen the consistency and robustness of the policy recommendations (Nikas et al., 2021). However, it is not always easy to compare outputs from different models, as it involves a laborious task of bringing together modeling communities with different backgrounds. To overcome these handicaps, the IAMC developed a time-series data template (Huppmann et al., 2023) which has been used in prominent multi-IAM studies, such as the presentation of the Shared Socio-economic Pathways (SSPs) (O'Neill et al., 2014), the design of the Representative Concentration Pathways (RCPs) (Moss et al., 2010), and the last two IPCC Assessment Reports (AR5 (Masson-Delmotte et al., 2021) and AR6 (Shukla, J. et al., 2022)), as well as the IPCC Special Report on Global Warming of 1.5°C (Masson-Delmotte et al., 2018) and the recent climate scenarios of the Network for Greening the Financial System (NGFS) (Richters et al., 2022). For these kind of assessments, it is essential that the outputs from the different models meet strict requirements and are reported in a standardized way to facilitate the comparison and multi-analysis (Skea et al., 2021).

One of the most extensively applied integrated assessment model is the Global Change Analysis Model (GCAM) (Calvin et al., 2019). GCAM is an open-source multi-sector model developed at the Joint Global Change Research Institute (JGCRI) designed to explore the linkages between energy, water, land, climate, and economics within a single computational system. It enables users to explore potential what-if type futures by dividing the world in 32 geopolitical regions and running in a 5-year time step. GCAM is in continuous development, with each new version increasing its accuracy by better representing and detailing existing elements, while adding new ones and fixing old ones (Binsted et al., 2022; Sampedro et al., 2022). Hence, the code to transform GCAM outputs into suitable outputs for model intercomparison should be adapted to each particular version/study. Otherwise, it becomes difficult to reproduce, automatize, and track changes (Stodden et al., 2018).

Here we present `gcamreport`, a powerful R-tool aligned with the principles of open science (Lin et al., 2020; Wilkinson et al., 2016), to guarantee the transparency of the produced outcomes by transforming GCAM outputs to the IAMC template requirements, making the

70 results directly applicable to multi-IAM studies (including upcoming IPCC reports). Moreover,  
 71 to overcome the limitations to reproduce the execution environment (e.g., packages or libraries),  
 72 gcamreport is also available within a [Docker](#) image, which already contains all the required  
 73 packages and facilitates the usage, ensuring interoperability and reproducibility ([Boettiger,](#)  
 74 [2015](#)).

75 Finally, to support the analysis of the model results, gcamreport includes a user-friendly  
 76 interface that allows to visualize the standardized outputs in tabular format, allowing the user  
 77 to subset the results by regions, scenarios, models, variables, and years, along with the option  
 78 to download the desired results. Moreover, the gcamreport user interface generates plots of  
 79 the selected variables within the same category, aggregated by region and/or sub-variables,  
 80 which can also be downloaded for more in-depth analysis.

## 81 **Functionality**

82 The gcamreport package consists of a set of functions divided into two different blocks. All  
 83 functions are described in a specific [documentation](#) supplemented by detailed tutorials.

- 84 ■ Dataset generation block: Transformation and saving of outputs from a created or  
 85 pre-loaded GCAM database to meet the IAMC formatting requirements.
- 86 ■ Interactive user block: Dataset visualization and manipulation, and figures generation.

87 To read the raw GCAM outputs, gcamreport uses [rgcam](#). This R package is part of the  
 88 GCAM-ecosystem, which is a set of complementary tools to the GCAM model that extend its  
 89 functionality and facilitate data management. In particular, rgcam allows to both read and  
 90 create a manageable data file containing the desired model outputs selected from the GCAM  
 91 results database.

92 For the correct performance of gcamreport internal functions, the package includes user-  
 93 modifiable constant values and mapping files, such as regional and sectorial aggregations,  
 94 as well as external files to compute additional calculations to produce some results that are  
 95 beyond the regular GCAM reporting (e.g., installed capacity). These additional calculations  
 96 are necessary to meet the IAMC reporting requirements (since not all models provide the same  
 97 type of outputs, but often through back-on-the-envelope calculations, harmonizing outputs  
 98 in this way improves the comparability of model results). Mapping files are automatically  
 99 loaded and used, but they can be customized and adjusted by the user if required by a specific  
 100 study as described in a detailed [R vignette](#). If the mapping files or the reporting template are  
 101 modified, it is recommended to save and tag the final used version to allow reusability and  
 102 reproducibility.

103 The output generated by the functions within the *dataset generation block* consists of an  
 104 RData dataset, a Comma-Separated Values (CSV) file, and a Microsoft Excel Open XML  
 105 Spreadsheet (XLSX), all of which are automatically saved unless the user specifies otherwise  
 106 with the `save_output` parameter. This ensures portability and format compatibility of the  
 107 output ([Krey, 2023](#)). Besides, the output generated by the *interactive user block* are both  
 108 CSV files and Portable Network Graphic (PNG) files, corresponding to the processed tabular  
 109 data and the generated figures, which are only saved if the user clicks on the corresponding  
 110 *download* button. This last block can be directly run with the RData dataset generated by the  
 111 former block, avoiding the need to re-create the reporting dataset, as detailed in this [example](#).

**Figure 2:** Interactive user interface visualization example. In a), see a tabular example and in b) see a plotting example.

Despite the optimization, the package still requires some performing time, mostly in order to create the project file from the given database. If the project file is already given, it takes less than a minute to produce the reporting dataset.

Lastly, the package will be updated simultaneously with the official GCAM releases, promoting the reusability and transparency. To keep track of the versions, there will be a gcamreport release by each GCAM version, tagged and named as documented in this [protocol](#). In the same line, some new features are planned for next releases, such as the reporting of hydrogen or refinery investments, or the generation of other types of plots in the user interface, in order to make the package more flexible and better adaptable to the needs of the scientific community. There are also plans to integrate the package into the GCAM-ecosystem suite of tools. Combining gcamreport with other tools in the ecosystem (such as [gcamextractor](#)) will allow GCAM users to obtain the model outputs in different formats, depending on their scientific needs.
